2.1 What is RNA-seq?

2.1 What is RNA-seq?

- RNA-seq is the high throughput sequencing of cDNA using NGS technologies
- RNA-seq works by **sequencing every RNA molecule** and profiling the expression of a particular gene by **counting** the number of time its transcripts have been sequenced.
- The summarized RNA-seq data is widely known as ***count table***

	Condition A			Condition B		
Gene1	4	0	2	12	14	13
Gene2	0	23	50	47	22	0
Gene3	0	2	6	13	11	15
...
GeneG	156	238	37	129	51	118

2.1 What is RNA-seq?

Briefly, long RNAs are first converted into a library of cDNA fragments through either RNA fragmentation or DNA fragmentation (see main text).

Sequencing adaptors (blue) are subsequently added to each cDNA fragment and a short sequence is obtained from each cDNA using high-throughput sequencing technology.

The resulting sequence reads are aligned with the reference genome or transcriptome, and classified as three types: exonic reads, junction reads and poly(A) end-reads. These three types are used to generate a base-resolution expression profile for each gene, as illustrated at the bottom; a yeast ORF with one intron is shown.

2.1 What is RNA-seq?

- Functional studies
 - Genome may be constant but an **experimental condition** has a pronounced effect on gene expression
 - ✓ e.g. Drug treated vs. untreated cell line
 - ✓ e.g. Wild type versus knock out mice
- Some molecular features can only be observed at the RNA level
 - Alternative isoforms, fusion transcripts, RNA editing
- Predicting transcript sequence from genome sequence is difficult
 - Alternative splicing, RNA editing, etc.

 - 3. Main challenges in RNA-seq**
 - 4. RNA-seq vs Microarrays**
 - 5. RNA-seq analysis pipeline(s)**
 - 6. Alignment**
 - 7. RNA-seq pipeline with R**

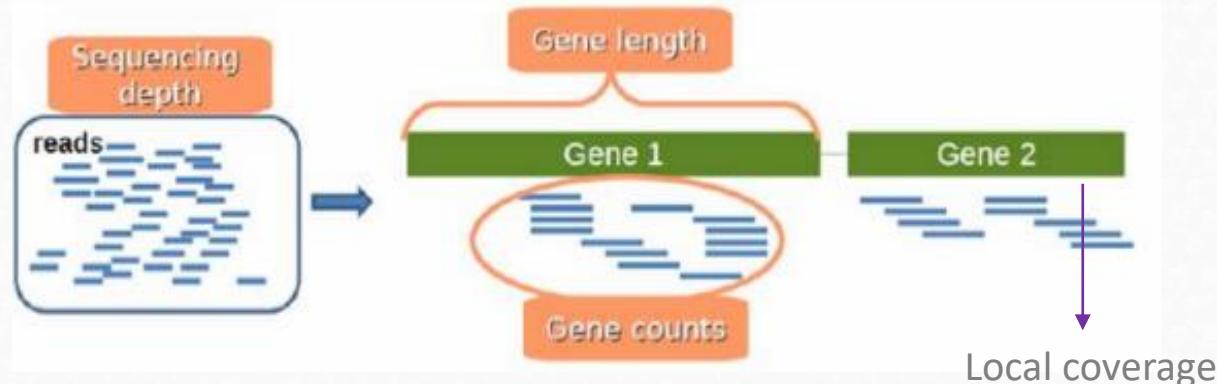

2.2 Basic key concepts?

Sequencing depth: Total number of reads mapped to the genome. ([Library size](#)) Could also be applied to samples.

Coverage: Number of reads mapped to a specific region (average of them if we are talking about the whole genome...)

Gene length: Number of bases that a gene has.

Gene counts: Number of reads mapping to that gene (expression measurement)

 - 6. Alignment**
 - 7. RNA-seq pipeline with R**

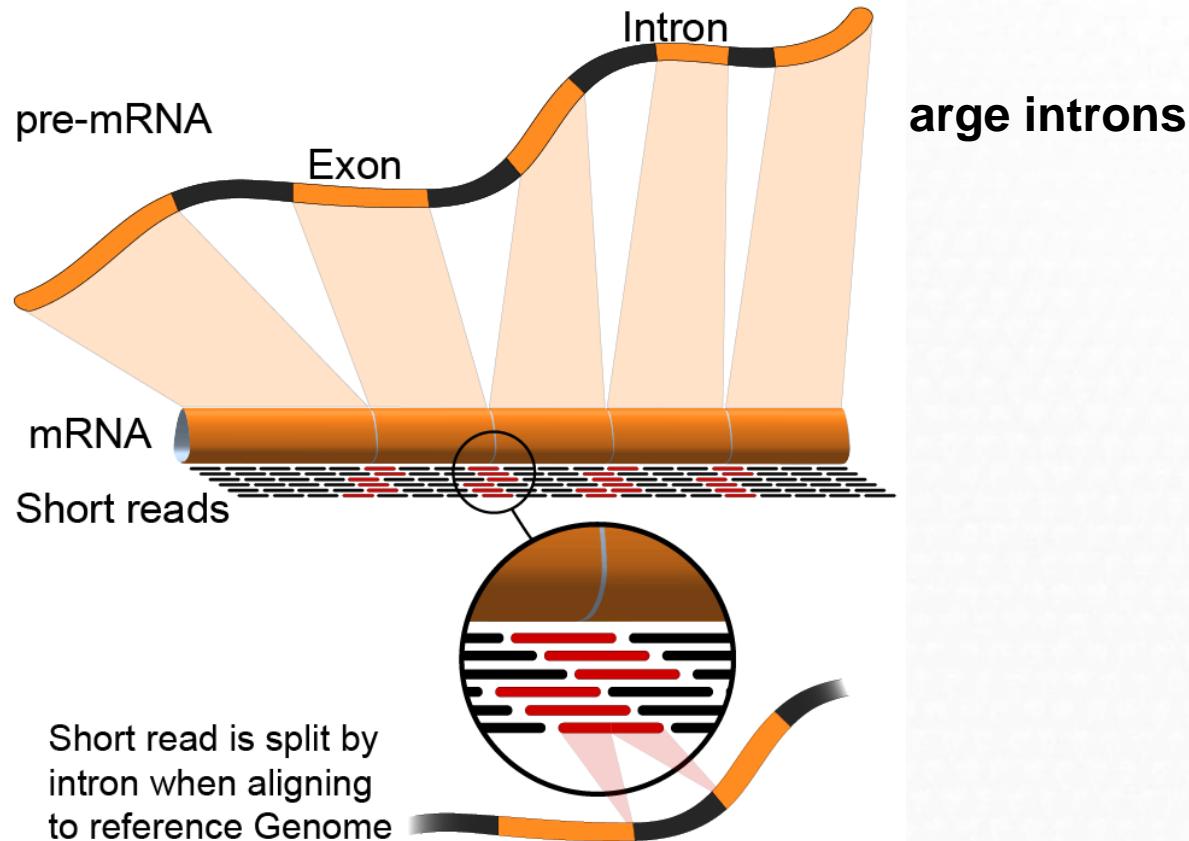

3.3 Main challenges in RNA-seq

- **Sample**
 - Purity? Quantity? Quality?
- **RNAs consist of small exons that may be separated by large introns**
 - Mapping reads to genome is challenging
 - Non-uniformity coverage of the genome

3.3 Main challenges in RNA-seq

- **Sample**
 - Purity? Quality control

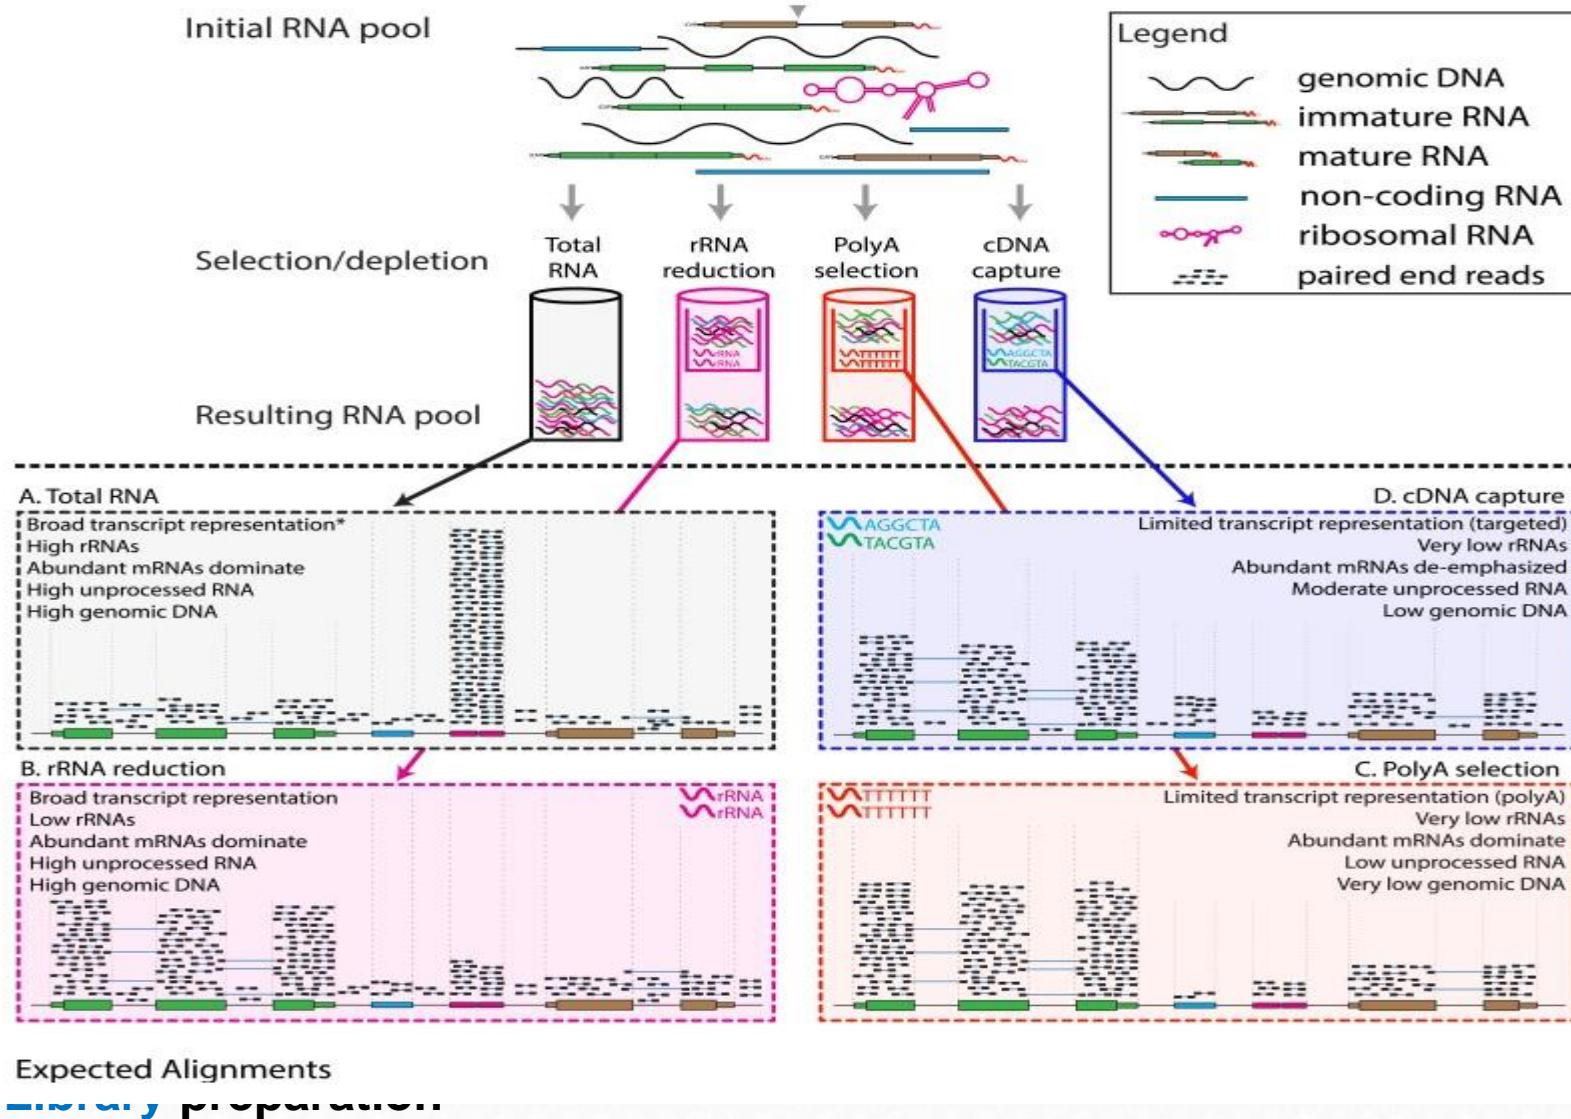

- **RNAs consist of pre-mRNA**
 - Mapping reads
 - Non-uniform

3.3 Main challenges in RNA-seq

- **Sample**
 - Purity? Quantity? Quality?
- **RNAs consist of small exons that may be separated by large introns**
 - Mapping reads to genome is challenging
 - Non-uniformity coverage of the genome
- **The relative abundance of RNAs vary wildly**
 - $10^5 - 10^7$ orders of magnitude
 - Since RNA sequencing works by random sampling, a small fraction of highly expressed genes may consume the majority of reads (rRNA)
- **RNAs come in a wide range of sizes**
 - Small RNAs must be captured separately
 - PolyA selection of large RNAs may result in 3' end bias
- **RNA is fragile compared to DNA (easily degraded)**
- **Library preparation**

3.3 Main challenges in RNA-seq

3.3 Main challenges in RNA-seq

- Independently of the software used, one needs to think about

2.4 RNA-seq vs Microarrays

PLoS One. 2013 Aug 20;8(8):e71462. doi: 10.1371/journal.pone.0071462. eCollection 2013.

Large scale comparison of gene expression levels by microarrays and RNAseq using TCGA data.

Guo Y¹, Sheng Q, Li J, Ye F, Samuels DC, Shyr Y.

Abstract

RNAseq and microarray methods are frequently used to measure gene expression level. While similar in purpose, there are fundamental differences between the two technologies. Here, we present the largest comparative study between microarray and RNAseq methods to date using The Cancer Genome Atlas (TCGA) data. **We found high correlations between expression data obtained from the Affymetrix one-channel microarray and RNAseq (Spearman correlations coefficients of ~0.8).** We also observed that the low abundance genes had poorer correlations between microarray and RNAseq data than high abundance genes. As expected, due to measurement and normalization differences, Agilent two-channel microarray and RNAseq data were poorly correlated (Spearman correlations coefficients of only ~0.2). By examining the differentially expressed genes between tumor and normal samples we observed reasonable concordance in directionality between Agilent two-channel microarray and RNAseq data, although a small group of genes were found to have expression changes reported in opposite directions using these two technologies. Overall, RNAseq produces comparable results to microarray technologies in term of expression profiling. The RNAseq normalization methods RPKM and RSEM produce similar results on the gene level and reasonably concordant results on the exon level. Longer exons tended to have better concordance between the two normalization methods than shorter exons.

2.4 RNA-seq vs Microarrays

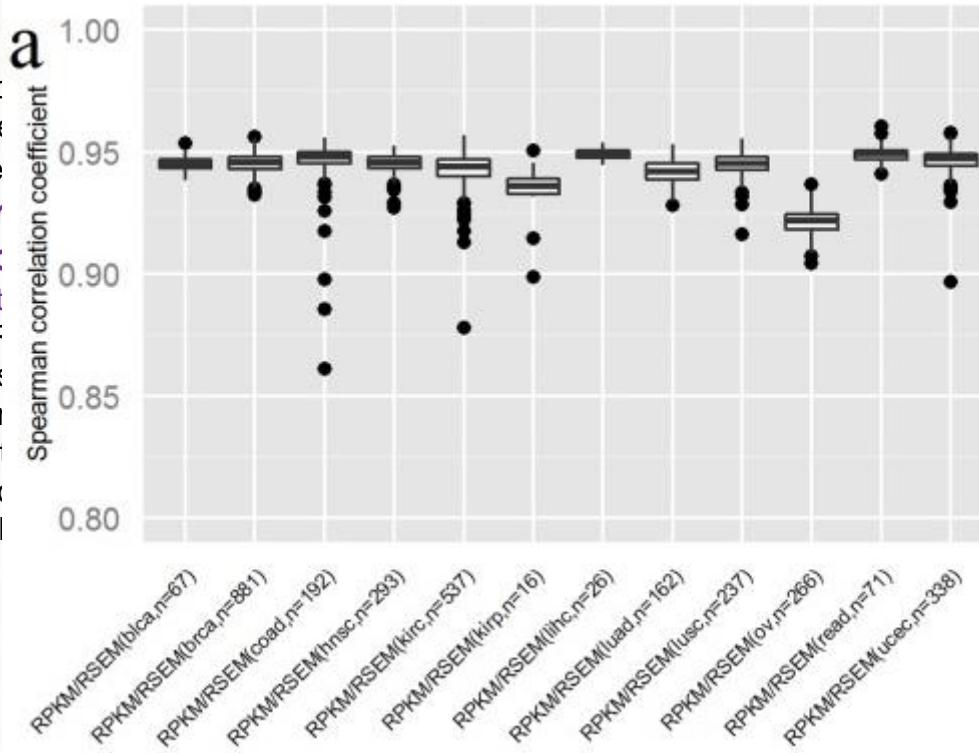

PLoS One. 2013 Aug 20;8(8):e71462. doi: 10.1371/journal.pone.0071462. eCollection 2013.

Large scale comparison of gene expression levels by microarrays and RNAseq using TCGA data.

Guo Y¹, Sheng Q, Li J, Ye F, Samuels DC, Shyr Y.

Abstract

RNAseq and microarray are two fundamental different technologies for measuring gene expression levels. While RNAseq measures gene expression levels directly, microarray measures mRNA levels by hybridizing complementary DNA probes. RNAseq and microarray have different strengths and weaknesses. RNAseq has higher resolution and can measure gene expression levels at the transcript level. Microarray has higher sensitivity and can measure gene expression levels at the genomic level. Both technologies have their own advantages and disadvantages. RNAseq is more expensive than microarray, but it provides more detailed information about gene expression levels. Microarray is less expensive than RNAseq, but it provides less detailed information about gene expression levels. RNAseq and microarray are both useful for gene expression analysis, but they have different strengths and weaknesses.

While similar in purpose, there are some differences between microarray and RNAseq.

high correlations

microarray and RNAseq (Spearman)

Microarray had poorer correlations between microarray and RNAseq than RNAseq. This was due to normalization differences, Agilent two-channel microarray had a lower correlation coefficient (~0.2) compared to RNAseq (~0.9). By examining the directionality of gene expression changes, we found that microarray and RNAseq reported in opposite directions for some genes. This suggests that microarray and RNAseq may have different results on the gene level and reasonably well between the two normalization methods than RNAseq.

2.4 RNA-seq vs Microarrays

Comparison of RNA-Seq and Microarray in Transcriptome Profiling of Activated T Cells

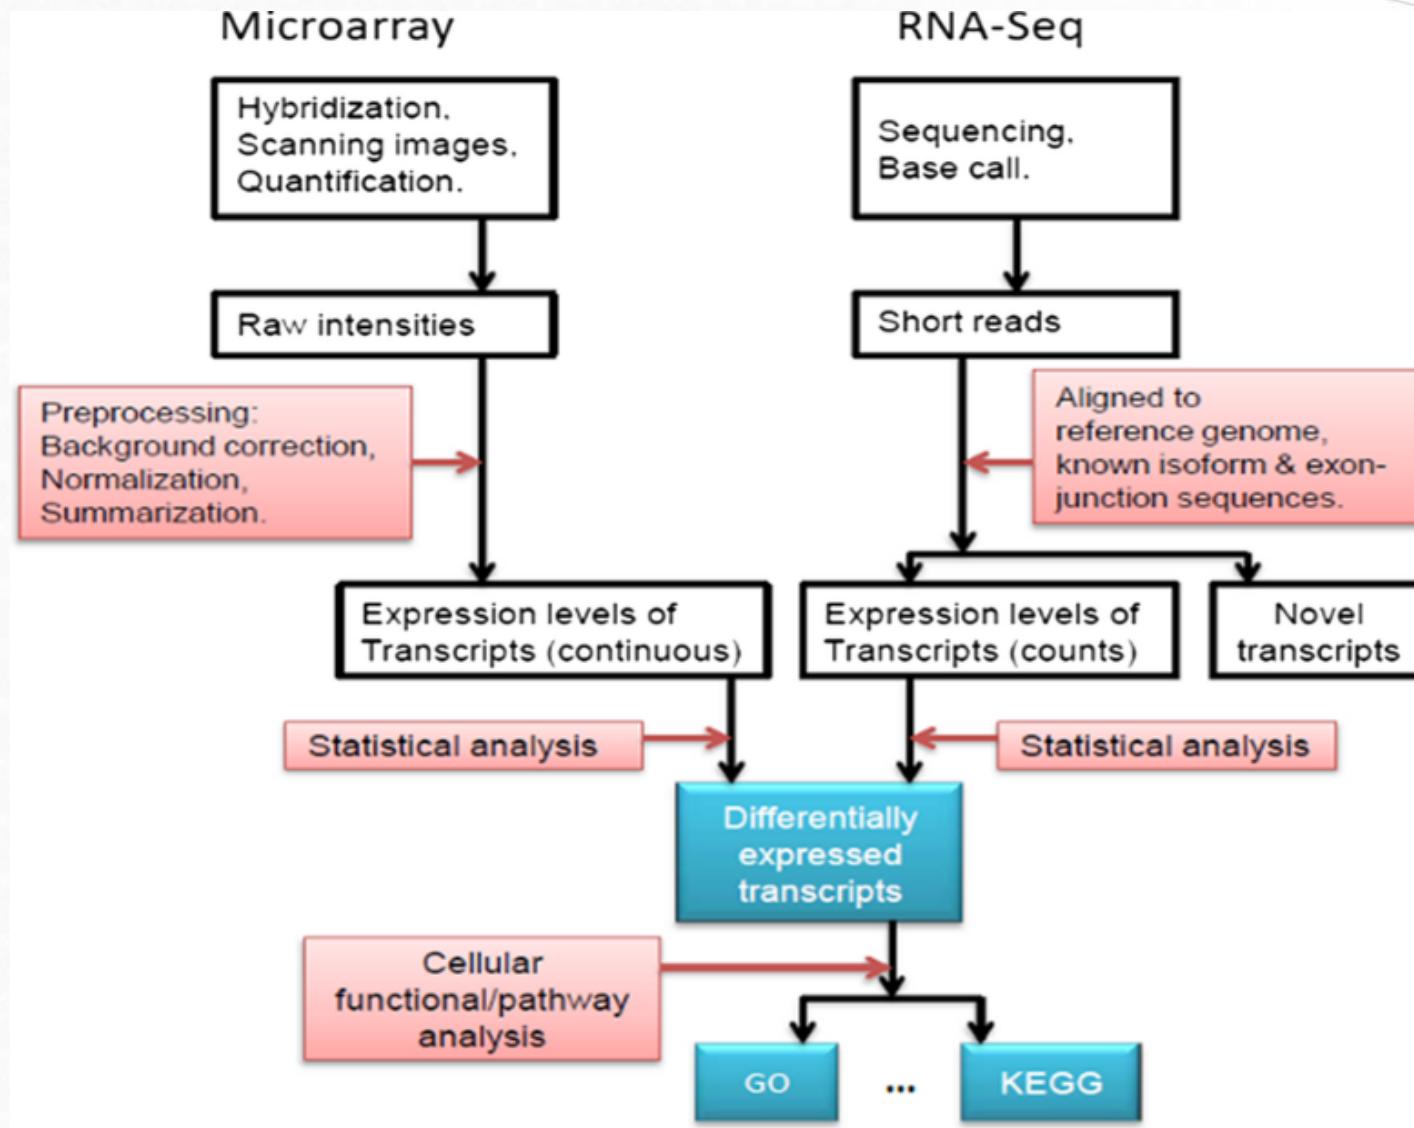

Shanrong Zhao , Wai-Ping Fung-Leung, Anton Bittner, Karen Ngo, Xuejun Liu 

Published: January 16, 2014 • DOI: 10.1371/journal.pone.0078644

- RNA-Seq was superior in detecting low abundance transcripts
- also better detecting differentiating biologically isoforms
- RNA-Seq demonstrated a broader dynamic range than microarray.
- RNA-Seq avoid problems inherent to microarray probe performance

!!!The study try to demonstrate the benefits of RNA-Seq over microarray in transcriptome profiling

2.4 RNA-seq vs Microarrays

2.4 RNA-seq vs Microarrays

Pros and cons of both technologies

Microarrays

- 😊 Costs,
- 😊 well established methods,
small data
- 😢 Hybridization bias,
- 😢 sequence must be known

RNA-seq

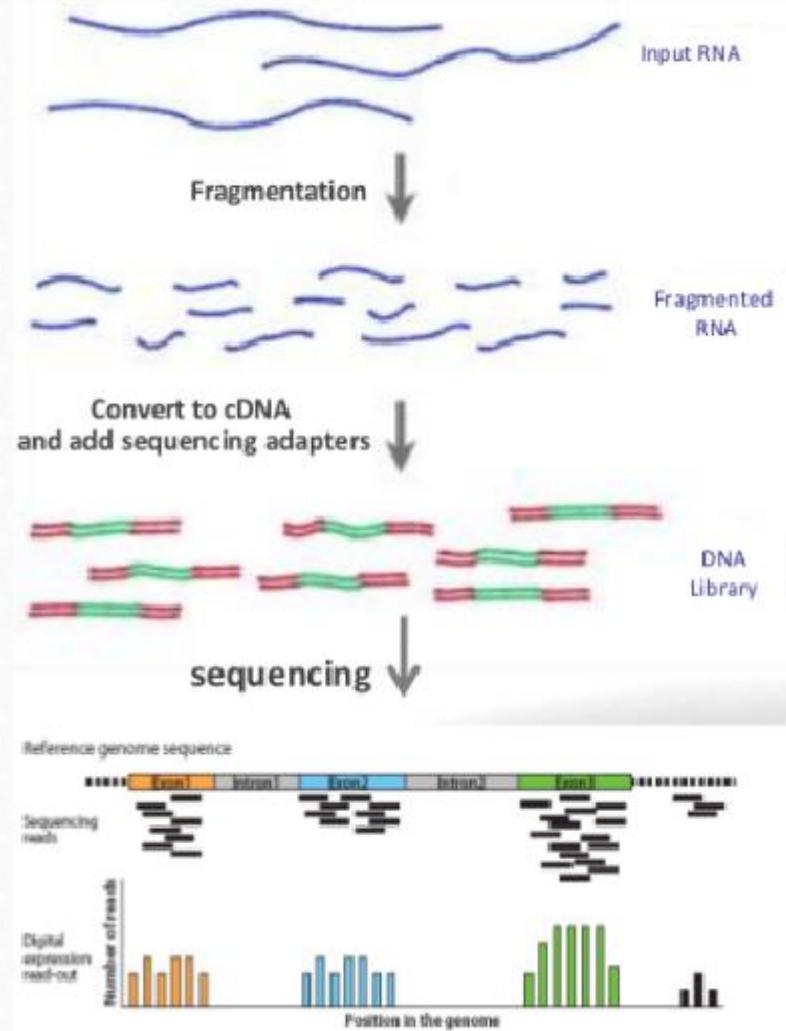

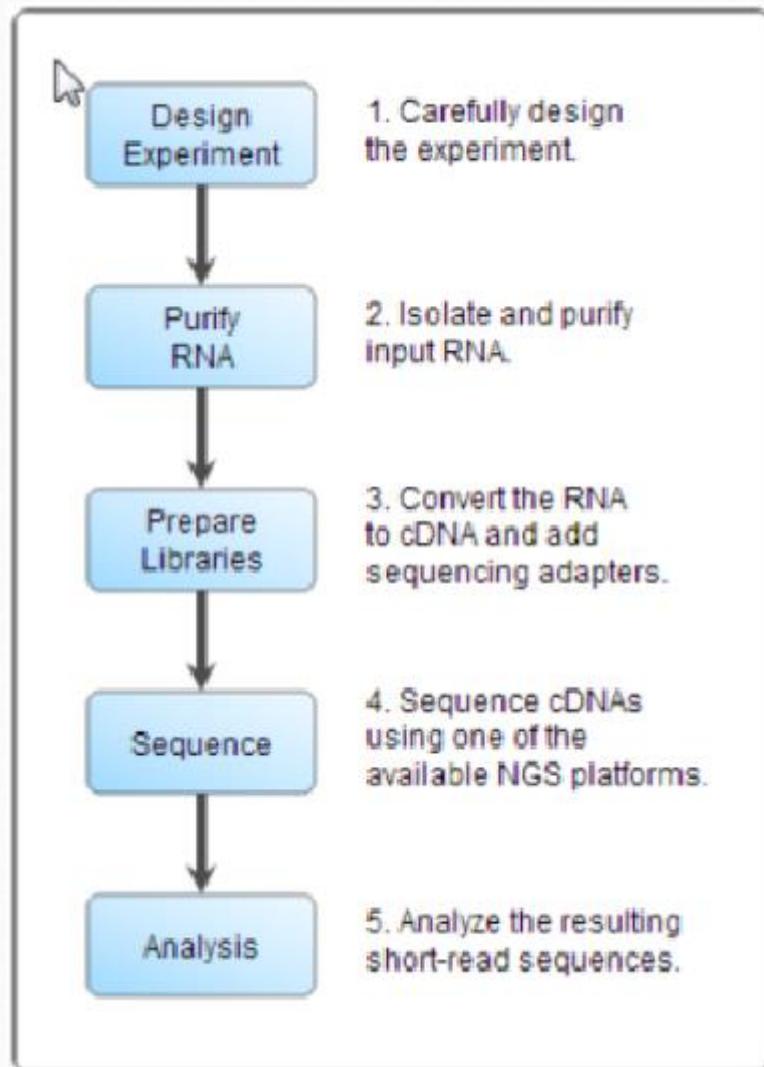

- 😊 High reproducibility,
- 😊 not limited to expression
- 😢 Costs,
- 😢 complexity of analysis

“**High correlation** between gene expression profiles generated by the two platforms.”

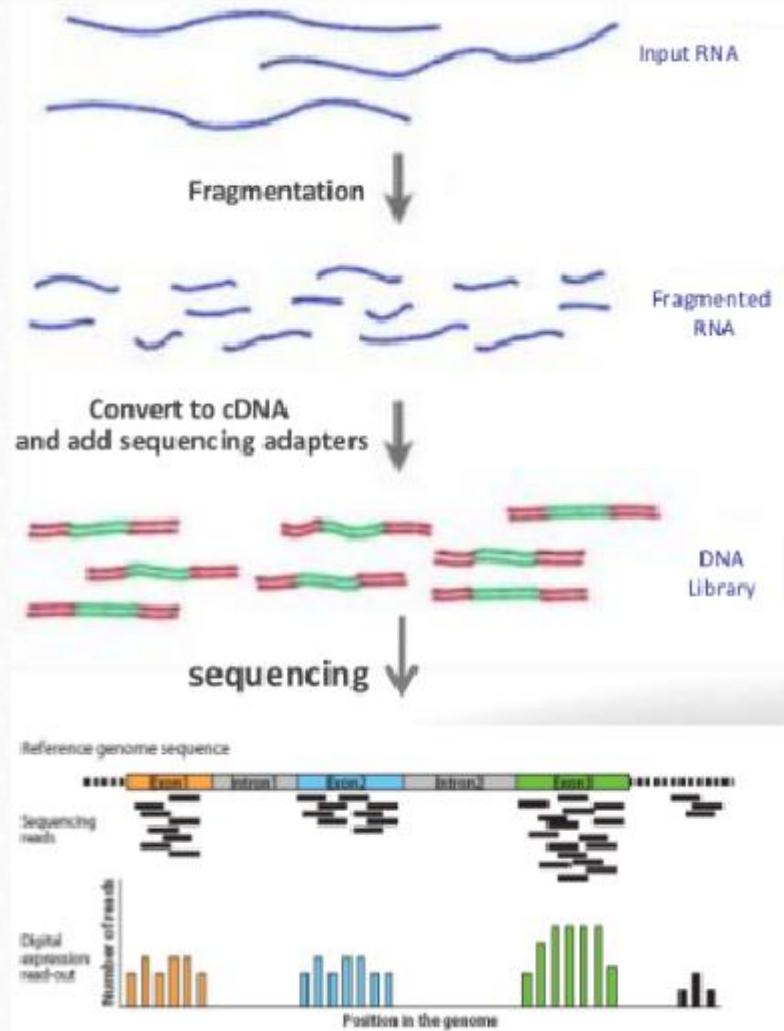

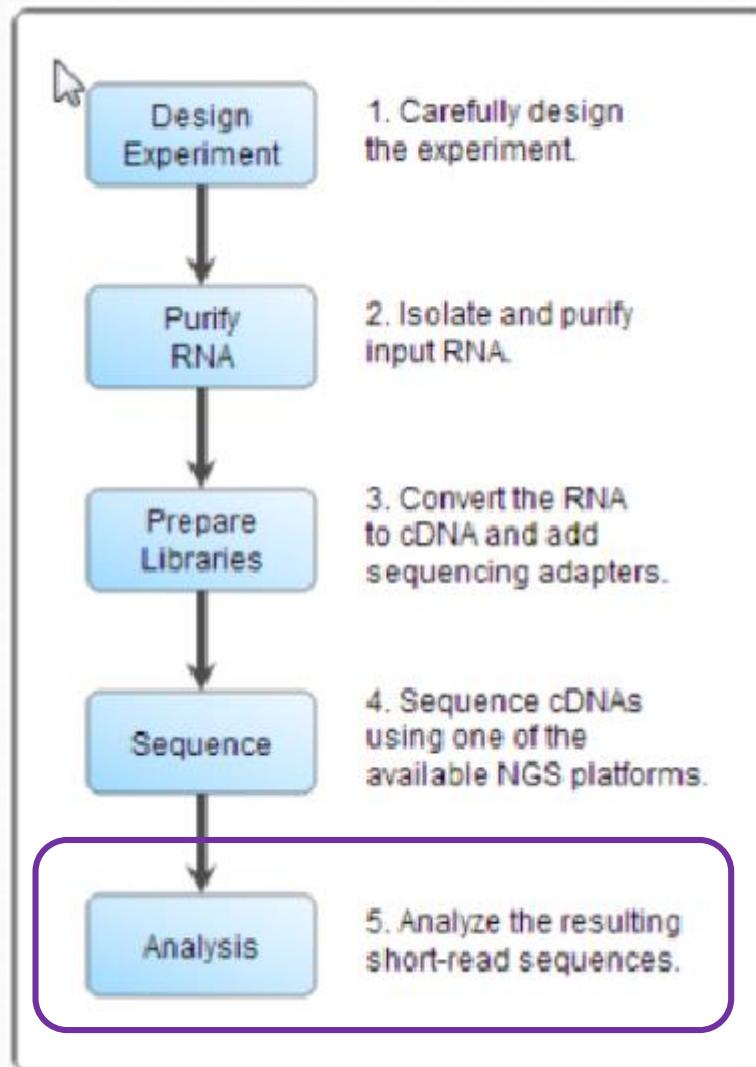

“RNA-Seq sequencing technology is new to most researchers, more expensive than microarray, **data storage is more challenging** and **analysis is more complex**.”

2.6 Alignment

What to map to?

Map to the genome, with knowledge of transcript annotations

- Well annotated genome reference is required.
- To effectively map to exon junctions, you need a mapping algorithm that can divide the sequencing reads and map portions independently.
- Identifying alternative transcript isoforms involves complex algorithms

2.6 Alignment

Which sequence mappers to use?

- RNASeq Alignment algorithm must be
 - Fast
 - Able to handle SNPs, indels, and sequencing errors
 - Maintain accurate quantification
 - Allow for introns for reference genome alignment (spliced alignment detection)

Which sequence mappers to use?

- RNASeq Alignment algorithm must be
 - Fast
 - Able to handle SNPs, indels, and sequencing errors
 - Maintain accurate quantification
 - Allow for introns for reference genome alignment (spliced alignment detection)
- Burrows-Wheeler Transform (BWT) mappers
 - Fast
 - Limited mismatches allowed (<3)
 - Limited indel detection ability
 - Examples: [Bowtie2](#), [BWA](#), [Tophat](#), [HISAT2](#)
 - Use cases: large and conserved genome and transcriptomes
- Hash Table mappers
 - Require large amount of RAM for indexing
 - More mismatches allowed
 - Indel detection
 - Examples: [GSNAP](#), [SHRiMP](#), [STAR](#)
 - Use case: highly variable or smaller genomes, transcriptomes

 - Require large amount of RAM for indexing
 - More mismatches allowed
 - Indel detection
 - Examples: GSAP, SHRiMP, STAR
 - Use case: highly variable or smaller genomes, transcriptomes

2.6 Alignment

Steps with TopHat

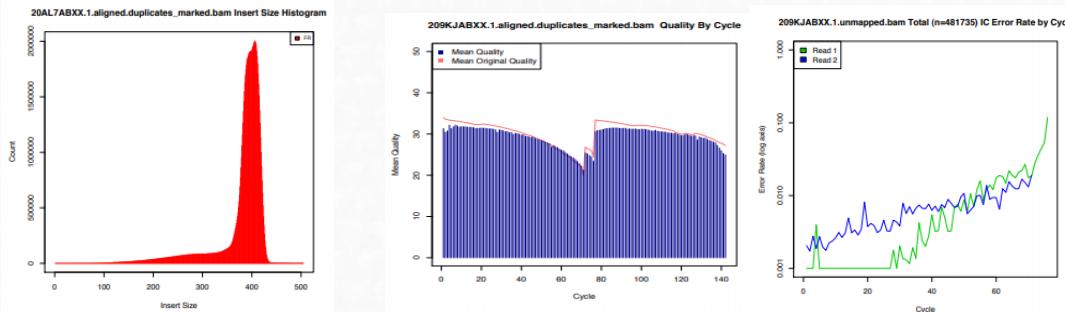

1. Unspliced reads are mapped to locate exons (with [Bowtie](#))
2. Unmapped reads are then split and aligned independently to identify exon

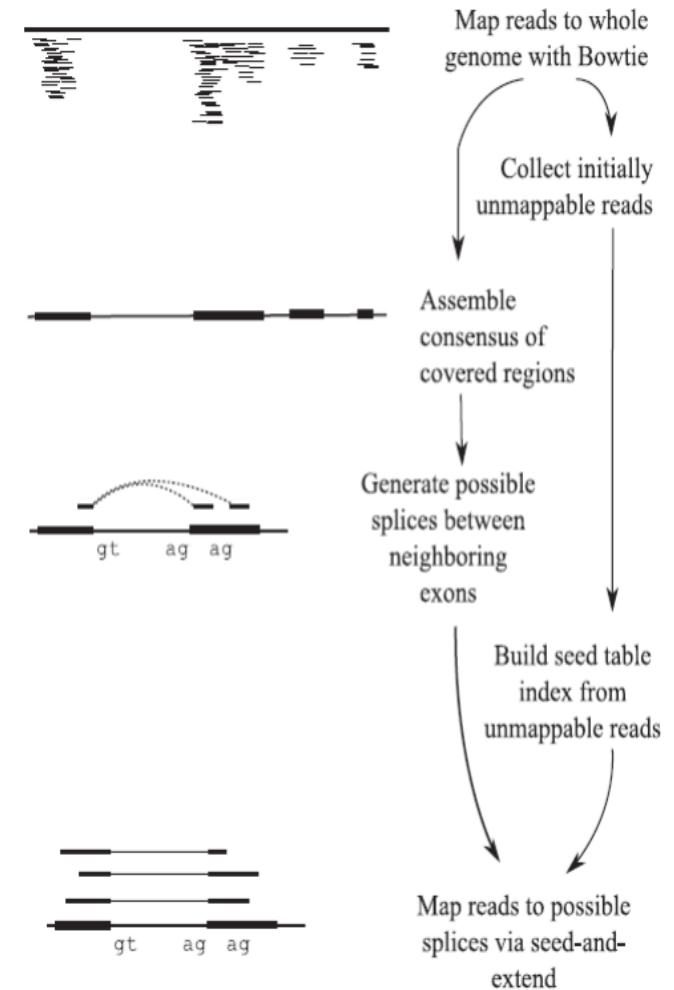

Important to check the quality of mapping process
(percentage of mapped reads)

Picard can be used for quality control of mapping

TopHat Pipeline

Alignment-independent quantification for RNA-Seq

- Alignment steps are computationally heavy and can be very time-consuming even with multi-threading.
- In 2014, **Sailfish** method, demonstrated that it was not necessary to actually align each read to the genome in order to obtain accurate transcript each read.

Brief Communication | Published: 20 April 2014

Sailfish enables alignment-free isoform quantification from RNA-seq reads using lightweight algorithms

Alignment-independent quantification for RNA-Seq

- Alignment steps are computationally heavy and can be very time-consuming even with multi-threading.
- In 2014, **Sailfish** method, demonstrated that it was not necessary to actually align each read to the genome in order to obtain accurate transcript each read.
- All you actually need to do is establish the most likely transcript for each read

1. shredding the transcriptome and reads into kmers (short overlapping sequences)
2. matching the transcriptome and read kmers (is a very fast and low memory usage)

Alignment-independent quantification for RNA-Seq

- Nowadays there exist various tools:
 - Salmon, Kallisto, Sailfish

PROS:

- Extremely Fast & Lightweight (can quantify 20 million reads in five minutes on a laptop computer)
- Easy to use

Alignment-independent quantification

Limitations of alignment-free tools in total RNA-seq quantification

Douglas C. Wu^{1,2} , Jun Yao^{1,2}, Kevin S. Ho^{1,2}, Alan M. Lambowitz^{1,2} and Claus O. Wilke^{1,3*}
Wu et al. BMC Genomics (2018) 19:510
<https://doi.org/10.1186/s12864-018-4869-5>

Conclusion: We have shown that alignment-free and traditional alignment-based quantification methods perform similarly for common gene targets, such as protein-coding genes. However, we have identified a potential pitfall in analyzing and quantifying lowly-expressed genes and small RNAs with alignment-free pipelines, especially when these small RNAs contain biological variations.

quantify 20% of the transcriptome in a reasonable amount of time (within 24 h) and requires only a few dollars on a laptop computer)

Title	Human Airway Smooth Muscle Transcriptome Changes in Response to Asthma Medications
Organism	Homo sapiens
Experiment type	Expression profiling by high throughput sequencing
Summary	Rationale: Asthma is a chronic inflammatory airway disease. The most common medications used for its treatment are β 2-agonists and glucocorticosteroids, and one of the primary tissues that these drugs target in the treatment of asthma is the airway smooth muscle. We used RNA-Seq to characterize the human airway smooth muscle (HASM) transcriptome at baseline and under three asthma treatment conditions. Methods: The Illumina TruSeq assay was used to prepare 75bp paired-end libraries for HASM cells from four white male donors under four treatment conditions: 1) no treatment; 2) treatment with a β 2-agonist (i.e. Albuterol, 1 μ M for 18h); 3) treatment with a glucocorticoid (i.e. Dexamethasone (Dex), 1 μ M for 18h); 4) simultaneous treatment with a β 2-agonist and glucocorticoid, and the libraries were sequenced with an Illumina Hi-Seq 2000 instrument. The Tuxedo Suite Tools were used to align reads to the hg19 reference genome, assemble transcripts, and perform differential expression analysis using the protocol described in https://github.com/blancahimes/taffeta
Overall design	mRNA profiles obtained via RNA-Seq for four primary human airway smooth muscle cell lines that were treated with dexamethasone, albuterol, dexamethasone+albuterol or were left untreated.

PLoS One. 2014 Jun 13;9(6):e99625. doi: 10.1371/journal.pone.0099625. eCollection 2014.

RNA-Seq transcriptome profiling identifies CRISPLD2 as a glucocorticoid responsive gene that modulates cytokine function in airway smooth muscle cells.

You can create it with a spreadsheet software

2.7 RNA-seq pipeline with R

Generate count matrices

Once the reads have been aligned, there are a number of tools that can be used to count the number of reads/fragments that can be assigned to genomic features for each sample. These often take as input SAM/BAM alignment files and a file specifying the genomic features, e.g. a GFF3 or GTF file specifying the gene models.

function	package	framework	output	<i>DESeq2</i> input function
<i>summarizeOverlaps</i>	<i>GenomicAlignments</i>	R/Bioconductor	<i>SummarizedExperiment</i>	<i>DESeqDataSet</i>
<i>featureCounts</i>	<i>Rsubread</i>	R/Bioconductor	matrix	<i>DESeqDataSetFromMatrix</i>
<i>tximport</i>	<i>tximport</i>	R/Bioconductor	list of matrices	<i>DESeqDataSetFromTximport</i>
<i>htseq-count</i>	<i>HTSeq</i>	Python	files	<i>DESeqDataSetFromHTSeq</i>

2.7 RNA-seq pipeline with R

Generate count matrices

Here we will proceed using `summarizeOverlaps`, using the *Run* column in the sample table, we construct the full paths to the files we want to perform the counting operation on:

```
filenames <- file.path(indir, paste0(sampleTable$Run, "_subset.bam"))
file.exists(filenames)
filenames

```

Generate count matrices

Note: make sure that the chromosome names of the genomic features in the annotation you use are consistent with the chromosome names of the reference used for read alignment. Otherwise, the scripts might fail to count any reads to features due to the mismatching names. For example, a common mistake is when the alignment files contain chromosome names in the style of `1` and the gene annotation in the style of `chr1`, or the other way around. See the `seqlevelsStyle` function in

Generate count matrices

- We indicate in Bioconductor that these files are BAM files using the BamFileList function from the Rsamtools package that provides an R interface to BAM files.
- Here we also specify details about how the BAM files should be treated, e.g., only process 2 million reads at a time

```
library("Rsamtools")
bamfiles <- BamFileList(filenames, yieldSize=2000000)
```

2.5 Defining gene models

Next, we need to read in the gene model that will be used for counting reads/fragments. We will read the gene model from an Ensembl GTF file (Flicek et al. 2014), using `makeTxDbFromGFF` from the `GenomicFeatures` package. GTF files can be downloaded from Ensembl's FTP site or other gene model repositories. A `TxDb` object is a database that can be used to generate a variety of range-based objects, such as exons, transcripts, and genes. We want to make a list of exons grouped by gene for counting read/fragments.

```
library("GenomicFeatures")
gtffile <- file.path(indir,"Homo_sapiens.GRCh37.75_subset.gtf")
txdb <- makeTxDbFromGFF(gtffile, format = "gtf", circ_seqs = character())
txdb
```

2.7 RNA-seq pipeline with R

TxDb object:

```
# Db type: TxDb
# Supporting package: GenomicFeatures
# Data source: C:/Users/rgonz/Documents/R/win-
    library/4.0/airway/extdata/Homo_sapiens.GRCh37.75_subset.gtf
# Organism: NA
# Taxonomy ID: NA
# miRBase build ID: NA
# Genome: NA
# Nb of transcripts: 65
# Db created by: GenomicFeatures package from Bioconductor
# Creation time: 2020-12-04 17:40:04 +0100 (Fri, 04 Dec 2020)
# GenomicFeatures version at creation time: 1.40.1
# RSQLite version at creation time: 2.2.1
# DBSCHEMAVERSION: 1.2
```

2.7 RNA-seq pipeline with R

The following line produces a *GRangesList* of all the exons grouped by gene (Lawrence et al. 2013). Each element of the list is a *GRanges* object of the exons for a gene.

```
ebg <- exonsBy(txdb, by="gene")
ebg
GRangesList object of length 20:
$ENSG00000009724
GRanges object with 18 ranges and 2 metadata columns:

-----
seqinfo: 1 sequence from an unspecified genome; no seqlengths
```

2.6 Read counting step

After these preparations, the actual counting is easy. The function `summarizeOverlaps` from the `GenomicAlignments` package will do this. This produces a `SummarizedExperiment` object that contains a variety of information about the experiment, and will be described in more detail below.

Note: If it is desired to perform counting using multiple cores, one can use the `register` and `MulticoreParam` or `SnowParam` functions from the `BiocParallel` package before the counting call below. Expect that the `summarizeOverlaps` call will take at least 30 minutes per file for a human RNA-seq file with 30 million aligned reads. By sending the files to separate cores, one can speed up the entire counting process.

2.7 RNA-seq pipeline with R

```
library("GenomicAlignments")
library("BiocParallel")
library("DESeq2")

register(SerialParam())
```

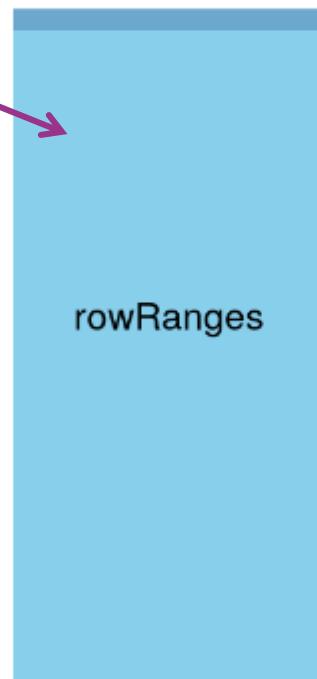

The following call creates the SummarizedExperiment object with counts:

```
se <- summarizeOverlaps(features=ebg, reads=bamfiles,
                         mode="Union",
                         singleEnd=FALSE,
                         ignore.strand=TRUE,
                         fragments=TRUE )
```

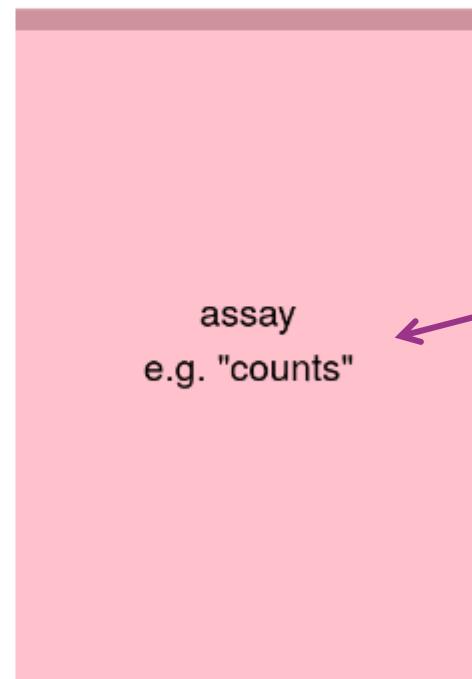

2.7 RNA-seq pipeline with R

We have created the object **gse** with three matrices:

- “**counts**” - the estimated fragment counts for each gene and sample,
- “**abundance**” - the estimated transcript abundances in TPM, and
- “**length**” - the effective gene lengths which include changes in length due to biases as well as due to transcript usage.

2.7 RNA-seq pipeline with R

Analysis of differential expressed genes

Now he will began with full count matrix corrsponding to all the samples and all the data

```
data(gse)
gse

```

- to make sure that the object contains all the necessary information about the samples

```
colData(gse)
DataFrame with 8 rows and 3 columns
  names    donor   condition
  <factor> <factor>   <factor>
SRR1039508 SRR1039508 N61311 Untreated
SRR1039509 SRR1039509 N61311 Dexamethasone
SRR1039512 SRR1039512 N052611 Untreated
SRR1039513 SRR1039513 N052611 Dexamethasone
SRR1039516 SRR1039516 N080611 Untreated
SRR1039517 SRR1039517 N080611 Dexamethasone
SRR1039520 SRR1039520 N061011 Untreated
SRR1039521 SRR1039521 N061011 Dexamethasone
```

2.7 RNA-seq pipeline with R

- We can rename our variables if we want. Let's use cell to denote the donor cell line, and dex to denote the treatment condition

```
gse$cell <- gse$donor  
gse$dex <- gse$condition
```

- We can also change the names of the levels. It is critical when one renames levels to not change the order. Here we will rename "Untreated" as "untrt" and "Dexamethasone" as "trt":

```
levels(gse$dex) <- c("untrt", "trt")
```

2.7 RNA-seq pipeline with R

- We can construct a DESeqDataSet object that will be the starting point of the analysis. We add an appropriate design for the analysis:

```
library("DESeq2")
dds <- DESeqDataSet(gse, design = ~ cell + dex)
```

4 Exploratory analysis and visualization

4.1 Pre-filtering the dataset

Our count matrix with our *DESeqDataSet* contains many rows with only zeros, and additionally many rows with only a few fragments total. In order to reduce the size of the object, and to increase the speed of our functions, we can remove the rows that have no or nearly no information about the amount of gene expression. Here we apply the most minimal filtering rule: removing rows of the *DESeqDataSet* that have no counts, or only a single count across all samples. Additional weighting/filtering to improve power is applied at a later step in the workflow.

2.7 RNA-seq pipeline with R

- It is recommended to filter for **lowly expressed genes** before differential expression testing.

- provide little evidence for differential expression and they interfere with some of the statistical approximations used
- Add to the multiple testing burden when estimating FDR, reducing power to detect differential expressed genes.

```
##Filter out those rows without any count
> nrow(dds)
[1] 58294
> dds <- [rowSums(counts(dds)) > 1, ]
Error: inesperado '[' in "dds <-["
> dds <- dds[rowSums(counts(dds)) > 1, ]
> nrow(dds)
[1] 31604
```

4.2 The variance stabilizing transformation and the rlog

Many common statistical methods for exploratory analysis of multidimensional data, for example clustering and *principal components analysis* (PCA), work best for data that generally has the same range of variance at different ranges of the mean values.

For RNA-seq counts, however, the expected variance grows with the mean (genes with *highest* counts show the largest absolute differences between samples)

A simple and often used strategy to avoid this is to take the logarithm of the normalized count values plus a pseudocount of 1

DESeq2 offers transformations for count data that stabilize the variance across the mean: the ***variance stabilizing transformation (VST)***

2.7 RNA-seq pipeline with R

```
vsd <- vst(dds, blind = FALSE)
```

```
> head(assay(vsd), 3)
```

	SRR1039508	SRR1039509	SRR1039512	SRR1039513	SRR1039516	SRR1039517	SRR1039520	SRR1039521

4.3 Sample distances

A useful first step in an RNA-seq analysis is often to assess overall similarity between samples: Which samples are similar to each other, which are different? Does this fit to the expectation from the experiment's design?

```
#Sample distances
```

```
sampleDists <- dist(t(assay(vsd)))
sampleDists
```

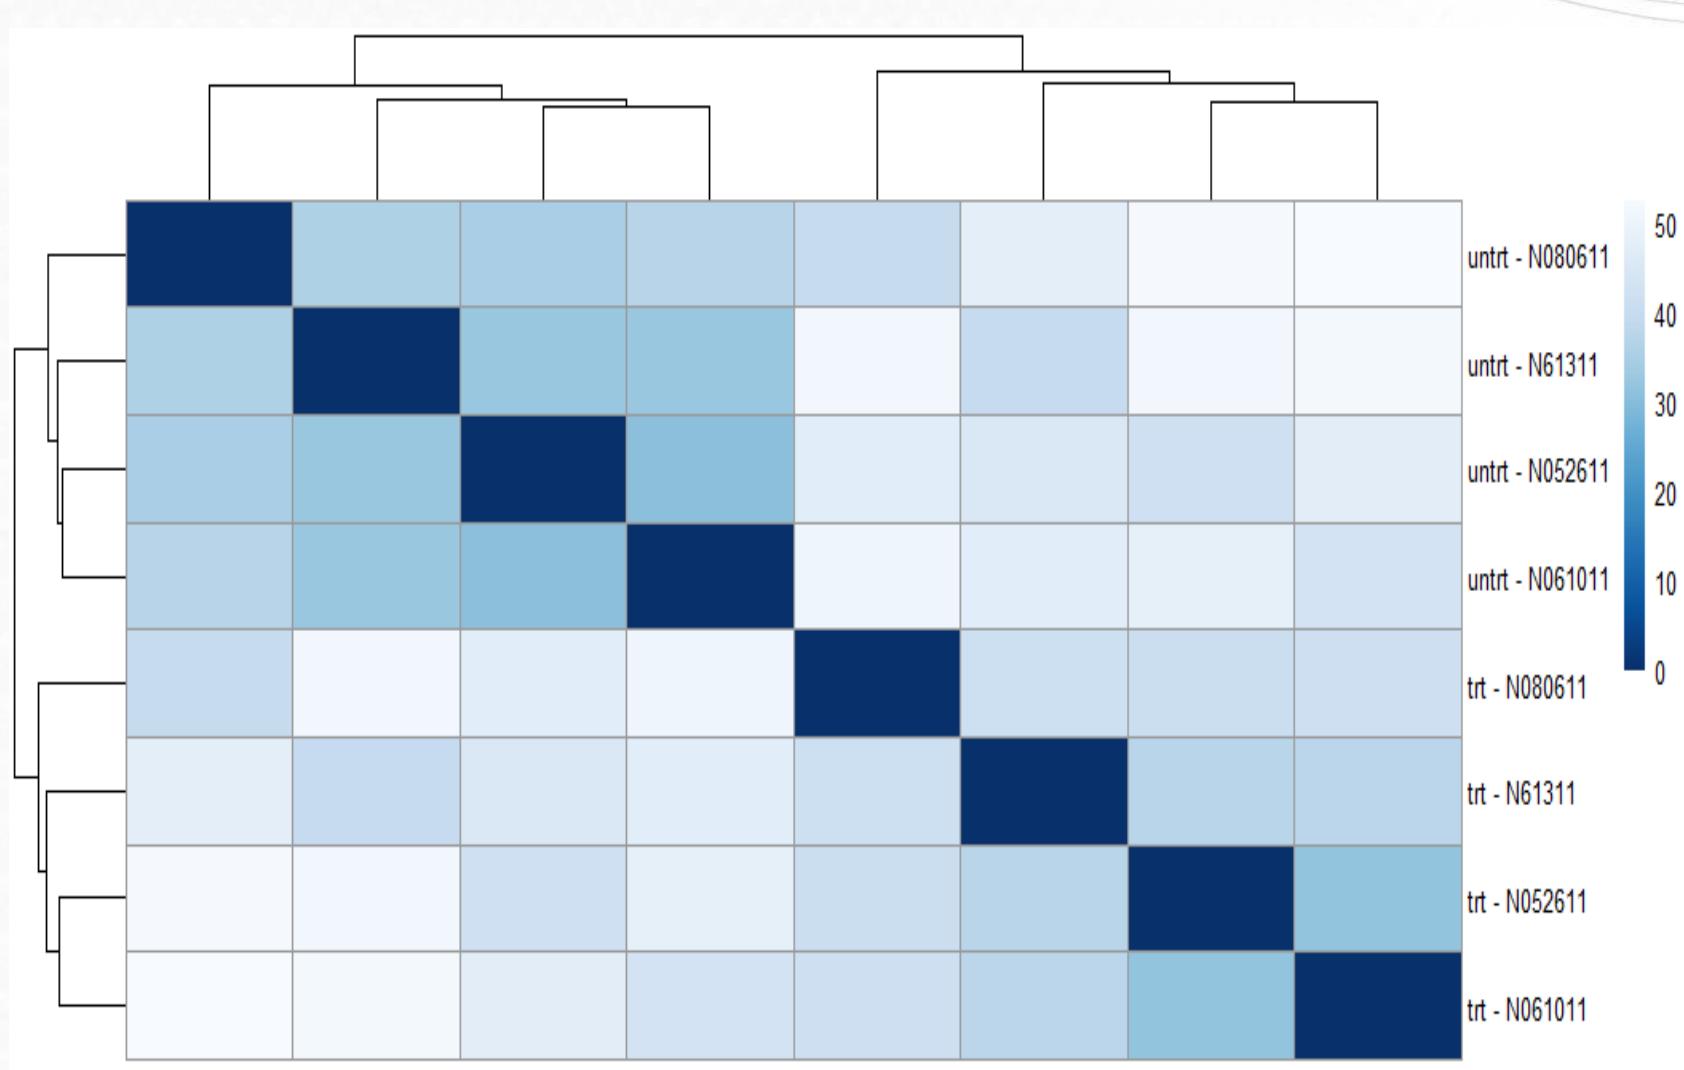

2.7 RNA-seq pipeline with R

Heatmap + Hierarchical Clustering

```
library("pheatmap")
library("RColorBrewer")

sampleDistMatrix <- as.matrix( sampleDists )
rownames(sampleDistMatrix) <- paste( vsd$dex, vsd$cell, sep = " - " )
colnames(sampleDistMatrix) <- NULL
colors <- colorRampPalette( rev(brewer.pal(9, "Blues")) )(255)
pheatmap(sampleDistMatrix,
         clustering_distance_rows = sampleDists,
         clustering_distance_cols = sampleDists,
         col = colors)
```

```
dds <- DESeq(dds, parallel =TRUE)
```

estimating size factors

using 'avgTxLength' from assays(dds), correcting for library size
estimating dispersions

gene-wise dispersion estimates: 1 workers

mean-dispersion relationship

final dispersion estimates, fitting model and testing: 1 workers

Data Normalization

The counts of mapped reads for each gene is proportional to the expression of RNA (“interesting”) in addition to many other factors (“uninteresting”).

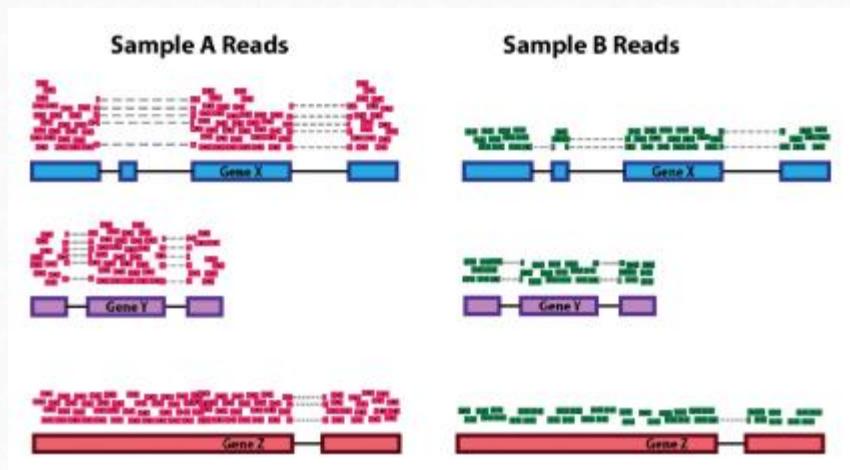

Normalization is the process of scaling raw count values to account for the “uninteresting” factors.

2.7 RNA-seq pipeline with R

Main factors often considered during normalization are:

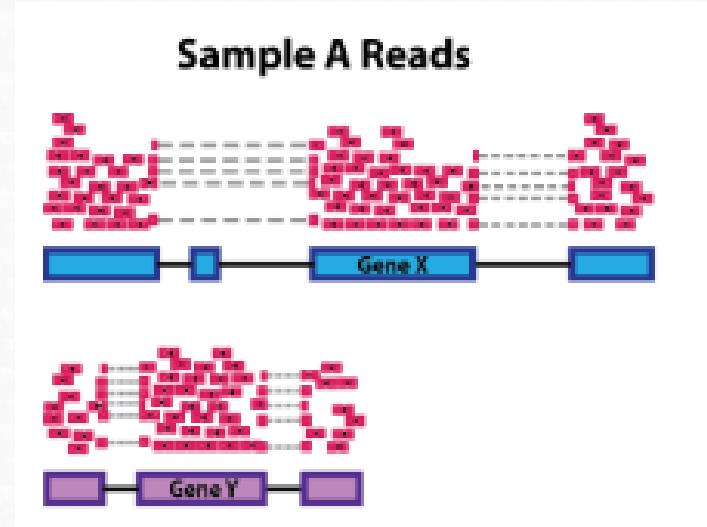

1. **Sequencing depth:** total number or reads mapped to the genome

2.7 RNA-seq pipeline with R

Main factors often considered during normalization are:

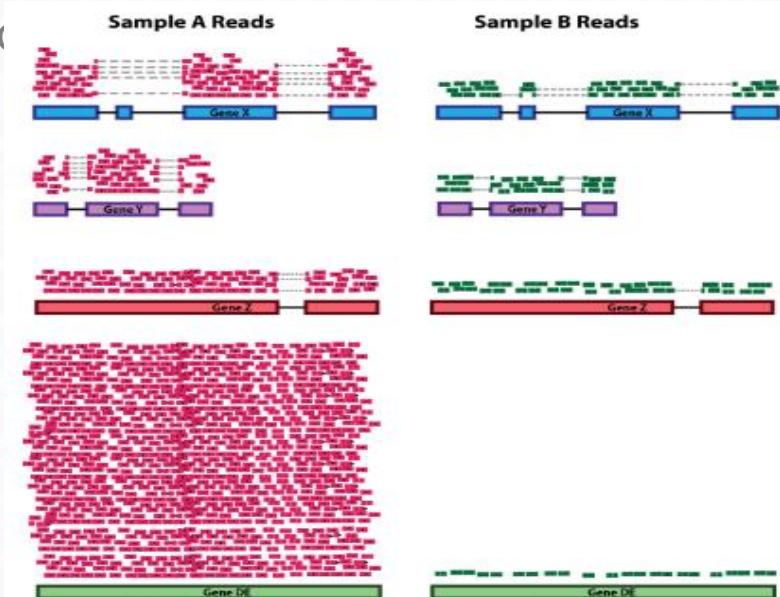

2. **Gene length:** Accounting for gene length is necessary for comparing expression between different genes within the same sample.

2.7 RNA-seq pipeline with R

Main factors often considered during normalization are:

3. **RNA composition:** A few highly differentially expressed genes between samples, differences in the number of genes expressed between samples, or presence of contamination can skew some types of normalization.

2.7 RNA-seq pipeline with R

Normalization method	Description	Accounted factors	Recommendations for use
CPM (counts per million)	counts scaled by total number of reads	sequencing depth	gene count comparisons between replicates of the same samplegroup; NOT for within sample comparisons or DE analysis
TPM (transcripts per kilobase million)	counts per length of transcript (kb) per million reads mapped	sequencing depth and gene length	gene count comparisons within a sample or between samples of the same sample group; NOT for DE analysis
RPKM/FPKM (reads/fragments per kilobase of exon per million reads/fragments mapped)	similar to TPM	sequencing depth and gene length	gene count comparisons between genes within a sample; NOT for between sample comparisons or DE analysis
DESeq2's median of ratios [1]	counts divided by sample-specific size factors determined by median ratio of gene counts relative to geometric mean per gene	sequencing depth and RNA composition	gene count comparisons between samples and for DE analysis ; NOT for within sample comparisons
EdgeR's trimmed mean of M values (TMM) [2]	uses a weighted trimmed mean of the log expression ratios between samples	sequencing depth, RNA composition, and gene length	gene count comparisons between and within samples and for DE analysis

2.7 RNA-seq pipeline with R

Check the results

```
res <- results(dds, contrast=c("dex","trt","untrt"))
res
```

log2 fold change (MLE): **dex trt vs untrt**

2.7 RNA-seq pipeline with R

metadata with information on the meaning of the columns:

```
mcols(res, use.names = TRUE)
```

DataFrame with 6 rows and 2 columns

		type	description
		<character>	<character>
baseMean	intermediate	mean of normalized counts for all samples	
log2FoldChange	results	log2 fold change (MLE): dex trt vs untrt	
lfcSE	results	standard error: dex trt vs untrt	
stat	results	Wald statistic: dex trt vs untrt	
pvalue	results	Wald test p-value: dex trt vs untrt	
padj	results	BH adjusted p-values	

2.7 RNA-seq pipeline with R

We can also summarize the results with the following line of code:

```
summary(res)
```

```
out of 31604 with nonzero total read count
adjusted p-value < 0.1
LFC > 0 (up)      : 2373, 7.5%
LFC < 0 (down)    : 1949, 6.2%
outliers [1]       : 0, 0%
low counts [2]     : 14706, 47%
(mean count < 9)
[1] see 'cooksCutoff' argument of ?results
[2] see 'independentFiltering' argument of ?results
```

2.7 RNA-seq pipeline with R

Other comparisons: Here we extract results for the log2 of the fold change of one cell line over another

```
results(dds, contrast = c("cell", "N061011", "N61311"))
```

log2 fold change (MLE): cell N061011 vs N61311

Wald test p-value: **cell N061011 vs N61311**

DataFrame with 31604 rows and 6 columns

Volcano plot

6.3 Gene clustering

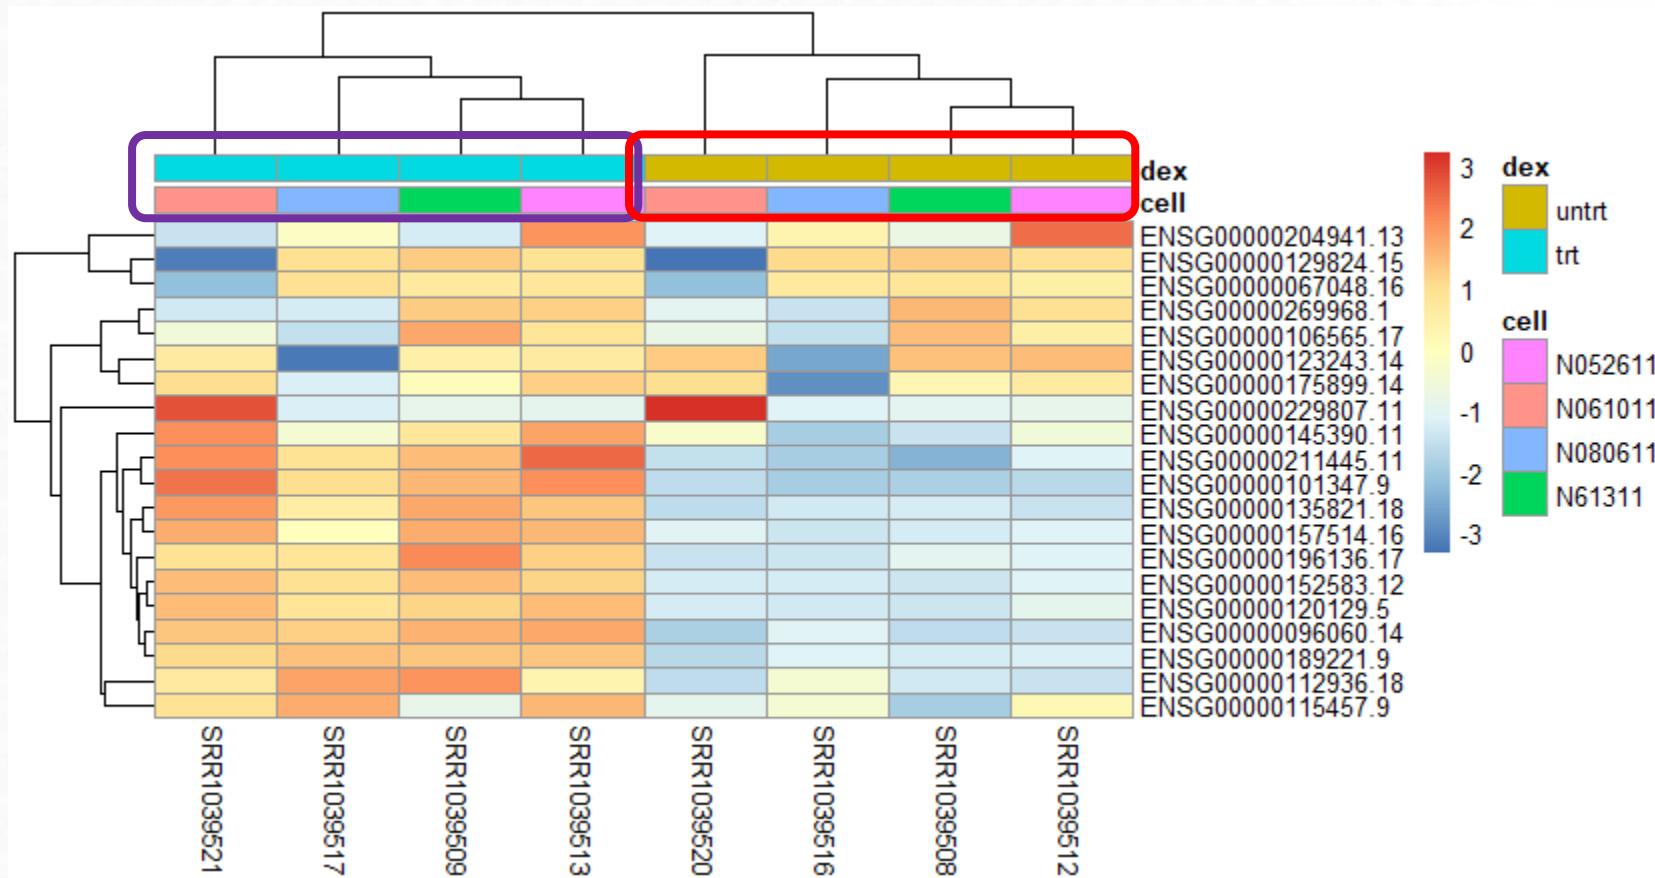

In the sample distance heatmap made previously, the dendrogram at the side shows us a hierarchical clustering of the samples. Such a clustering can also be performed for the genes. Since the clustering is only relevant for genes that actually carry a signal, one usually would only cluster a subset of the most highly variable genes. Here, for demonstration, let us select the 20 genes with the highest variance across samples. We will work with the VST data.

```
library("genefilter")
topVarGenes <- head(order(rowVars(assay(vsd))), decreasing = TRUE), 20)
mat <- assay(vsd)[ topVarGenes, ]
mat <- mat - rowMeans(mat)
anno <- as.data.frame(colData(vsd)[, c("cell", "dex")])
pheatmap(mat, annotation_col = anno)
```

2.7 RNA-seq pipeline with R

2.7 RNA-seq pipeline with R

7 Annotating and exporting results

Our result table so far only contains the Ensembl gene IDs, but alternative gene names may be more informative for interpretation. Bioconductor's annotation packages help with mapping various ID schemes to each other. We load the *AnnotationDbi* package and the annotation package *org.Hs.eg.db*:

```
library("AnnotationDbi")
library("org.Hs.eg.db")

ens.str <- substr(rownames(res), 1, 15)
res$symbol <- mapIds(org.Hs.eg.db,
                      keys=ens.str,
                      column="SYMBOL",
                      keytype="ENSEMBL",
                      multiVals="first")
res$entrez <- mapIds(org.Hs.eg.db,
                      keys=ens.str,
                      column="ENTREZID",
                      keytype="ENSEMBL",
                      multiVals="first")
resOrdered <- res[order(res$pvalue),]
head(resOrdered)
```

2.7 RNA-seq pipeline with R

7.1 Exporting results

You can easily save the results table in a CSV file that you can then share or load with a spreadsheet program such as Excel. The call to `as.data.frame` is necessary to convert the `DataFrame` object (`IRanges` package) to a `data.frame` object that can be processed by `write.csv`. Here, we take just the top 100 genes for demonstration.

```
resOrderedDF <- as.data.frame(resOrdered)[1:100, ]  
write.csv(resOrderedDF, file = "results.csv")
```
